INet for Network Integration

Tuesday, 2 May 2023 16:30 (15)

Nowadays, network data integration is a demanding problem and still an open challenge, especially when dealing with large datasets. When collecting several data sets and heterogeneous data types on a given phenomenon of interest, the individual analysis of each data set will give only a particular view of such phenomenon. In contrast, integrating all the data will widen and deepen the results giving a more global view of the entire system.

We developed a novel statistical method named *INet algorithm*, for data integration based on weighted multi-layer networks. Under the assumption that the structure underneath the different layers has some similarity that we want to emerge in the integrated network, we generate a “consensus network” through an iterative procedure based on structure comparison, capable of pulling out important information about the phenomenon under study. The procedure tries to preserve common higher-order structures of the original networks in the integrated one, i.e. neighbourhood. Once obtained the consensus network, we compared it with the starting networks extracting “specific networks”, one for each layer, containing peculiar information of the single data type not present in all the others.

We tested our method on simulated networks to analyse the performance of our algorithm and we analyzed virus and vaccine gene co-expression networks to better understand infectious diseases.

Keywords

Integration Network, Consensus, Multilayer network

Topics

- Complex networks
